REMARKS

In an Office Action dated December 17, 2003, the Examiner objected to the Specification; rejected claims 4, 9, 10, 12, 17, 19, 20, 24, 29, 30, 32 and 34 under 35 U.S.C. 112, second paragraph, as indefinite; rejected claims 1, 2, 4-6, 9-15 and 17-21 under 35 U.S.C. 102(a) as anticipated by McLaughlin, "Objects, objects everywhere: Data binding from XML to Java, Part 1" (McLaughlin-1); rejected claims 3, 8, 12, 22-26 and 28-35 under 35 U.S.C. 103(a) a unpatentable over McLaughlin-1 in view of McLaughlin, Make classes from XML data: Data binding from XML to Java code, Part 2" (McLaughlin-2); rejected claims 7 and 16 under 35 U.S.C. 103(a) as unpatentable over McLaughlin-1 in view of Holman, "What's the Big Deal with XSL?" (Holman); and rejected claims 27 and 36 under 35 U.S.C. 103(a) as unpatentable over McLaughlin-1 in view of McLaughlin-2 and further in view of Holman.

Objection to the Specification

The Examiner objected to the use of the trademarks JAVA and XML. Applicants have amended the Specification by providing a Substitute Specification, in a manner believed to address the Examiner's objection. Specifically, "Java" (previously lower case) has been amended to appear in all capital letters. Additionally, where appropriate, phrases including JAVA and XML have been amended so that these trademarks are used as adjectives. In general, "JAVA" is a modifier of "programming environment", and "XML" is a modifier of "document description language". However, these terms are also used to describe things associated with the respective programming environment or document description language. For example, a "JAVA class" is an object class in the JAVA programming environment, and an "XML document" is a document in the XML document description language. Such shortened forms are commonly used in technical literature without any loss of comprehension, and applicants believe they are sufficiently understood and consistent with use as trademarks.

Docket No.: CA920000010US1

Serial No.:

Indefiniteness Rejections

Claim 17 has been amended to correct the minor informality noted. Claim 19 has been amended to correct lack of antecedent basis, in conformance with the Examiner's understanding of the limitation.

Various additional claims have been amended to correct the recitation of either JAVA or XML, consistent with the changes made to the Specification as explained above. However, with respect to the Examiner's objection to the use of trademarks in the claims, applicants respectfully traverse the rejection. JAVA is a programming language and environment originally developed by Sun Microsystems, which retains certain trademark rights in the name JAVA. However, the semantic specification of the programming language, and requirements for associated environmental entities such as JAVA compilers, are publicly available, and are well known. The claims do not recite that the JAVA programming environment, JAVA classes, or other elements, must originate from Sun Microsystems, or from any other particular source. The claims only recite that these elements comply with the well-established JAVA standard. There are thousands of programmers who write code in this language every day, relatively few of them employed by Sun Microsystems.. These are people of skill in the art, and they are capable of determining whether or not code is written in the JAVA language. It is, in fact, their job to do so. Moreover, there is no generic name for the JAVA language itself. It is simply one of numerous programming languages. These claims are no less definite that a claim reciting FORTRAN, COBOL, Pascal, C++, or any other programming language.

For essentially the same reasons, the use of XML as a qualifier in certain claims is sufficiently definite. XML is a publicly known and available standard for a document definition language. The claims require only that the recited XML elements conform to this standard, not that they come from any particular source. Accordingly, applicants submit that the claims, as amended, are sufficiently definite.

Docket No.: CA920000010US1

Serial No.:

Prior Art

Applicants claim a priority date, under 35 USC 119, of April 28, 2000. Both *McLaughlin-1* and *McLaughlin-2* were published after applicants' effective priority date, and therefore are not available as references against applicants' claims herein. Since all rejections relied on at least one of these references, the rejections can not stand.

In view of the foregoing, Applicants submit that the claims are now in condition for allowance and respectfully request reconsideration and allowance of all claims. In addition, the Examiner is encouraged to contact applicants' attorney by telephone if there are outstanding issues left to be resolved to place this case in condition for allowance.

Respectfully submitted,

APPENDIX A: MARKED-UP SUBSTITUTE SPECIFICATION

METHOD FOR DATA ACCESS CODE GENERATION

Field of the Invention

This invention relates in general to the field of computer software and more particularly to data access code generation utilizing templates.

Background of the Invention

The introduction of Java the JAVA programming environment, an object-oriented, multithreaded, portable, platform-independent, secure-programming environment, and its wide acceptance on the World Wide Web, requires programmers to migrate existing code and develop new code in Java the JAVA programming environment.

In object-oriented programming such as Java the JAVA programming environment, a class is a template definition of the methods and variables in a particular kind of object. For example, classes may be created for graphical user interface elements such as windows and tool bars and also for database interfaces. In general, classes provide an overall framework for developing an application program.

To address the requirements of commercial World Wide Web publishing and enable the expansion of World Wide Web technology, the World Wide Web Consortium has developed an Extensible Markup Language (XML) document definition language. XML document definition

language allows the creation of Java JAVA-based World Wide Web applications that were not

previously possible.

5

10

15

20

Traditionally, Java JAVA classes have been manually created requiring the user to have

knowledge of proprietary backend data access Application Program Interfaces (APIs). The

manual generation of Java JAVA classes can often be complex and very time-consuming

resulting in inconsistent code generation. Furthermore, for different APIs, specific Java JAVA

classes must be generated to provide access to the backend data.

Without a method and apparatus that improves the efficiency of generating data access

Java JAVA classes, the computer industry will continue to be plagued by inconsistent

implementations.

Summary of the Invention

According to the invention, there is provided a method and apparatus for data access code

generation. A data access code generator routine applies code generation templates to an

Extensible Markup Language (XML) document to generate the necessary data access Java JAVA

classes.

The XML document describes a data object and the mapping of the data object to Java

JAVA objects. The XML file must be created pursuant to the data model that exists in the

backend Application Program Interface (API) as each backend API generally requires specific

elements, attributes, and mappings to facilitate backend data access. The details of each data

model are defined in a data object Data Type Definition (DTD) document.

Docket No.: CA920000010US1

PATENT AMENDMENT

The code generation templates contain the support for the backend API data access calls

that are required to create the necessary Java <u>JAVA</u> classes from the XML file. The code

generation template is implemented in any transformation language that can convert an XML

document into Java JAVA code.

In operation, the data access code generator routine applies code generation templates to

an XML document containing a data object description, which creates the resulting Java JAVA

classes.

Other objects and advantages of the invention will become clear from the following

detailed description of the preferred embodiment, which is presented by way of illustration only

and without limiting the scope of the invention to the details thereof.

Brief Description of the Drawings

Further features and advantages will be apparent from the following detailed description,

given by way of example, of a preferred embodiment taken in conjunction with the accompanying

drawings, wherein:

Fig. 1 is a schematic block diagram of a data access code generator system constructed in

accordance with the preferred embodiment of the present invention.

Detailed Description of the Invention

Throughout the figures, like elements are indicated by like reference numbers.

Docket No.:

CA920000010US1

Serial No.:

Referring to Fig. 1, a data access code generator 10 of the preferred embodiment is depicted having a data access code generator routine 18 and code generation templates 16.

The data access code generator routine 18 takes the code generation templates 16 and the XML data object description 14 as inputs and produces the necessary data access Java JAVA classes 20.

The XML data object description 14 is a document created pursuant to the data model that exists in the backend. The data model is defined in a data object Document Type Definition (DTD) document 12. The data object DTD 12 contains all of the backend APIs definitions for the elements, attributes, and mappings that are required to provide access to the backend data at runtime. For example, a system that accesses a relational database backend will contain attributes and elements for column names and the mapping of the columns to Java JAVA attributes.

Every object description contained within the XML data object description 14 must conform to the elements, attributes, and mappings defined in the data object DTD 12. Further, the XML data object description 14 must be supported by the data access code generator routine 18.

The code generation templates 16 describe the code that is generated when the data access code generation routine 18 is invoked. The code generator templates 16 contain the following elements:

data access API calls for the backends that are supported in the data object DTD;

the implementation of system-wide policies such as caching, lazy initialization, logging, and the use of system infrastructure; and

Docket No.:

CA920000010US1

Serial No.:

10

15

rules for code generation.

In particular, the incorporation of rules for code generation allows for the simple, straightforward, and consistent generation of <u>Java JAVA</u> classes.

The code generation templates 16 are implemented in any transformation language that can convert an XML document into Java JAVA code. For example, the code generation templates 16 can be implemented in a transform mechanism such as Extensible Stylesheet Language (XSL), in which case the code generation templates 16 are actually XML files.

In operation, the method and apparatus for data access code generation commences with an author creating an XML data object description 14 describing a data object. The description of the data object must conform to the elements, attributes, and mappings defined in the data object DTD 12. The data access code generator routine 18 then takes the code generation templates 16 and the XML data object description 14 as inputs and produces the necessary data access Java JAVA classes 20 to provide access to the backend data at run-time.

One of the advantages of using a data access code generator routine 18 in conjunction with the code generation templates 16 is that programmers need not learn the proprietary backend APIs. The specific calls for each proprietary backend API are contained only in the code generation templates 16, where they are applied to the XML data object description 14 to create the necessary data access Java JAVA classes 20. This provides the further advantage of allowing the protection of proprietary information as programmers may be provided with the code generation templates 16 instead of the details of each proprietary backend API.

10

This method and apparatus also provide the advantage of allowing system-wide changes and enhancements to be made by simply regenerating the data access Java JAVA classes using modified code generation templates 16 or by simply modifying the data object description in the XML document 14.

Furthermore, through simply modifying the code generation templates 16, different policies can be applied without the need to edit each of the resulting data access Java JAVA classes 20.

Therefore, this method and apparatus for data access code generation provides the advantages of modifiability, extensibility, adaptation, and reusability. The modifiability of the data object description in the XML document and the code generator templates provides clear advantages over the manual creation and modification of Java JAVA classes. Consequently, a single XML data object description may be used in conjunction with several different code generation templates to create data access Java JAVA classes for different backend APIs. Furthermore, the code generation templates can be modified to include system modifications and the data access Java JAVA classes regenerated without the need to edit each resulting data access Java JAVA class.

Accordingly, while this invention has been described with reference to illustrative embodiments, this description is not to be construed in a limiting sense. Various modifications of the illustrative embodiments, as well as other embodiments of the invention, will be apparent to persons skilled in the art upon reference to this description.

For example, any object-oriented programming environment, such as C++, may be substituted for Java <u>Java</u> the JAVA programming environment. Furthermore, a single code generation template may be used, or a plurality of code generation templates may be used. Similarly, the
